Aims and Scope
Mission statement: To advance the scientific basis of human pathology by the publication (encouragement and dissemination) of high quality research (including molecular and translational studies) and thereby contribute to patient care. Manuscripts of original studies reinforcing the evidence base of modern diagnostic pathology, as well as broadsheets and guidelines with a solid evidence base will be considered. Consideration will also be given to reports of work in other fields relevant to the understanding of human pathology as well as manuscripts on the application of new methods and techniques in pathology. Submission of purely experimental articles is discouraged but manuscripts on experimental work applicable to diagnostic pathology are welcomed. Biomarker studies are welcomed but need to abide by strict rules (e.g., REMARK) of adequate sample size and relevant marker choice. Single marker studies on limited patient series without validated application will as a rule not be considered. Case reports will only be considered when they provide substantial new information with an impact on understanding disease or diagnostic practice.
was completely occupied by a solid, white, rubbery mass, with areas of necrosis and hemorrhage, which invaded the epididymis and the mediastinum testis. It had a solid and infiltrative growth pattern, exhibiting small blue round cells, crushing artefacts, rosette formation and severe cytological atypia. Positivity for CK8/18 and Synaptophysin (focal), CD99 and CD56 (strong and diffuse) was depicted.

Conclusion: Surgical resection is the treatment of choice for most cases of SM given their chemo-resistance. However, Pathologists should be aware of PNET SM and report it, as PNET-specific chemotheraphy was shown to be effective in treating this TGCT subtype.

Clinical case of multifocal primary tumour: Is the additional examination of the body required in case of malignant tumour of the urinary bladder?
V. Sikora*, A. Romanuik, M. Lyndin, R. Moskalenko, A. Pidubnyi
*Sumy State University, Dept. of Pathology, Ukraine

Objective: To determine the histogenesis of the urinary bladder (UB) neoplasia under suspected risk of multifocal pathology.
Method: Histological and immunohistochemical (IHC) examinations were carried out in several stages: 1) Hematoxylin and eosin; 2) CKpan, CD45 and Vimentin; 3) CKLMW, CKHMW, CK7 and 20; 4) AR, PSA, AMACR.
Results: The first stage, presented by histological examination of the formation in the UB revealed the growth of the undifferentiated malignant tumour. At the same time, the lesions with tubular-trabecular nature were revealed. For better understanding of the tumour nature the IHC examination was unremarkable, his laboratory values showed decreased haemoglobin (9.57 G/dl), increased WBC (10.2x1000, 80 % neutrophils), proteinuria, and normal Urea and Creatinine. CT scan revealed a mass involving the inferior lobe of the right kidney measuring 7 cm in greatest dimension. Right nephrectomy was performed on the patient.
Method: Gross examination showed a white-beige solid and well demarcated tumour, the renal tissue looked normal. The applied sections showed proliferation of packed trabecuclue, nests and cords of cells having cosinophilic granular cytoplasm and uniform nuclei with stippled chromatin, no mitotic activity neither necrosis could be seen despite generous sampling. The tumour growth was limited to the renal borders.
Results: Immunohistochemistry revealed positive staining for CD99, Chromogranin, and negative result for CD10 and CK7 with positive internal control, Ki-67 showed very low index (<1 %).
Conclusion: Microscopic morphology and the applied immunohistochemistry were consistent with well differentiated neuroendocrine tumour (carcinoid).

Retroperitoneal and pulmonary metastases from burned-out testicular germ cell tumour as initial clinical presentation: Report of two cases
V. Filipovski*, K. Kubelka-Sabit, D. Jasar, V. Janevska
*Clin. Hospital Acibadem/Sistina, Dept. of Histopathology, Skopje, F.Y. Republic of Macedonia

Objective: To present two cases of metastatic deposits from burned-out testicular germ cell tumours (GCTs) as initial clinical presentation of the disease.
Method: Case 1: Retroperitoneal necrotic tumour from a 40-year old male patient, and fragments from the lumbar vertebrae were submitted for analysis. Case 2: Core biopsy of a lung mass from a 26-year old male patient was received for analysis. Both cases were routinely processed and additional immunohistochemical analyses were performed.
Results: Case 1: Necrotic retroperitoneal tumour had only a few vital germ cell tumour cells positive for PLAP and CD30. In the testis, an area measuring 17 mm showed hyalinization, sclerosis and calcification with cystic structures presenting mature teratoma positive for cytokeratins 7...
